WHAT IS NEOPLASTIC PROGRESSION

- **Historical Background:** Empirical evidence has always suggested a neoplastic progression from relatively benign to invasive to metastatic disease.

  1. What initiates neoplasia? (INITIATION)

  2. How does it progress? (PROMOTION)

  3. How does it spread? (METASTASIS)

A Review in Time: The History of Breast Cancer

Sox11 regulates mammary tumour-initiating and metastatic capacity in *Brca1*-deficient mouse mammary tumour cells

Siu Man Tsang, Hyojin Kim, Erik Oliemuller, Richard Newman, Naa-Anyima Boateng, Naomi Guppy and Beatrice A. Howard*

ABSTRACT

Little is known about the role of Sox11 in the regulation of mammary progenitor cells. Sox11 is expressed by mammary bud epithelial cells during embryonic mammary gland development and is not detected in mammary epithelial cells after birth. As Sox11 is an oncofetal gene, we investigated the effects of reducing Sox11 levels in embryonic mammary progenitor cells and found that Sox11 regulates

(Zvelebil et al., 2013). We have recently shown that SOX11 confers features of multipotency, impairs differentiation processes and alters tropism of ER− breast cancer cells to metastatic sites (Oliemuller et al., 2020). Although a number of studies have shown that Sox11 is expressed in mammary stem cells during embryonic mouse mammary development, it is not known whether it has any functional role in regulating normal embryonic mammary progenitor cells (Chung et al., 2019; Makarem et al., 2013;

Reactivation of multipotency by oncogenic PIK3CA induces breast tumour heterogeneity

Alexandra Van Keymeulen[1]*, May Yin Lee[1]*, Marielle Ousset[1], Sylvain Brohée[2], Sandrine Rorive[3,4], Rajshekhar R. Giraddi[1], Aline Wuidart[1], Gaëlle Bouvencourt[1], Christine Dubois[1], Isabelle Salmon[3,4], Christos Sotiriou[2], Wayne A. Phillips[5,6] & Cédric Blanpain[1,7]

Breast cancer is the most frequent cancer in women and consists of heterogeneous types of tumours that are classified into different histological and molecular subtypes[1,2]. *PIK3CA* and *P53* (also known as *TP53*) are the two most frequently mutated genes and are associated with different types of human breast cancers[3]. The cellular origin and the mechanisms leading to *PIK3CA*-induced tumour heterogeneity remain unknown. Here we used a genetic approach in mice to define the cellular origin of *Pik3ca*-derived tumours and the impact of mutations in this gene on tumour heterogeneity. Surprisingly, oncogenic *Pik3ca*^{H1047R} mutant expression at physiological levels[4] in basal cells using keratin (K)5-CreER^{T2} mice induced the formation of luminal oestrogen receptor (ER)-positive/progesterone receptor (PR)-positive tumours, while its expression in luminal cells using K8-CReER^{T2} mice gave rise to luminal ER^{+}PR^{+} tumours or basal-like ER^{-}PR^{-} tumours. Concomitant deletion of *p53* and expression of *Pik3ca*^{H1047R} accelerated tumour development and induced more aggressive mammary tumours. Interestingly, expression of *Pik3ca*^{H1047R} in unipotent basal cells gave rise to luminal-like cells, while its expression in unipotent luminal cells gave rise to basal-like

upon expression of the *Pik3ca*^{H1047R} mutant in the mammary gland is currently unknown.

To determine whether breast tumour heterogeneity is determined by the cancer cell of origin, we developed a genetic strategy allowing the expression of the oncogenic *Pik3ca* mutant at physiological levels using Cre-inducible *Pik3ca*^{H1047R} knock-in mice[4], specifically in basal cells (BCs) using K5-CreER^{T2} or in luminal cells (LCs) using K8-CreER^{T2} mice[14] and followed their fate and tumorigenic potential over time. Tamoxifen (TAM) was administered at a dose that does not impair long-term mammary gland development and homeostasis, and resulted in the specific labelling of about 20% of BCs (Extended Data Fig. 1) in 4–5-week-old K5-CreER^{T2}/*Pik3ca*^{H1047R} mice (Fig. 1a). While it has been suggested that the mammary gland contains bipotent basal stem cells[15,16], our data using K5-CreER^{T2} knock-in or K14-rtTA/TetO-Cre mice, despite the labelling of 20–50% of BCs, showed no contribution of BCs to the luminal lineage (Extended Data Fig. 1). Further lineage-tracing studies that label all BCs or all LCs will be required to determine whether the discrepancy between the different

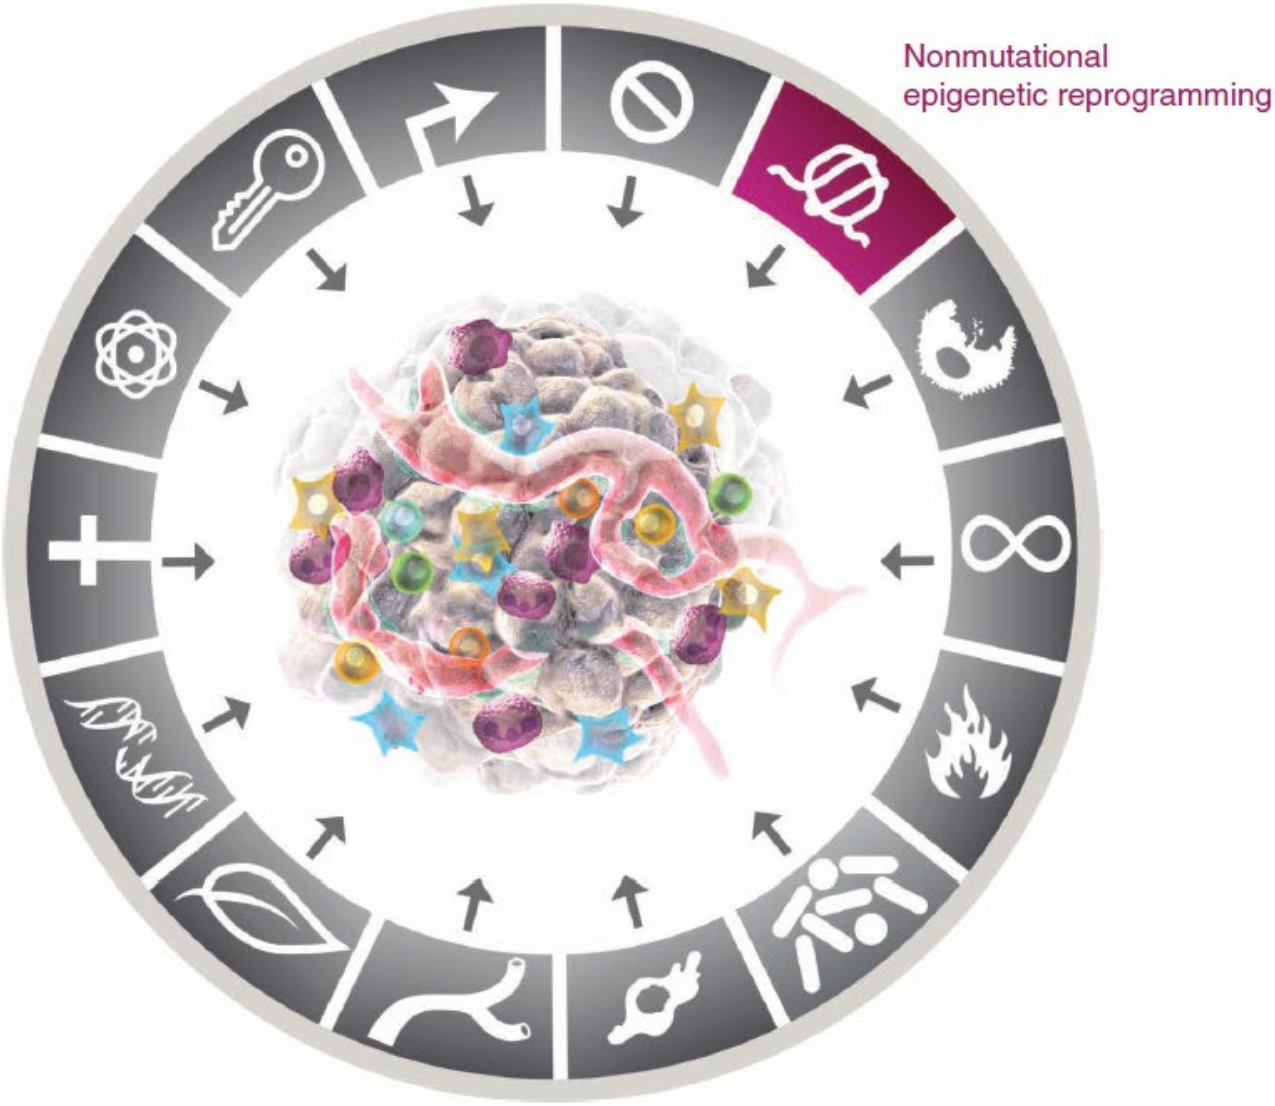

Figure 3. Nonmutational epigenetic reprogramming. Much as during embryogenesis and tissue differentiation and homeostasis, growing evidence makes the case that instrumental gene-regulatory circuits and networks in tumors can be governed by a plethora of corrupted and co-opted mechanisms that are independent from genome instability and gene mutation.

The Origins of Phenotypic Heterogeneity in Cancer

Guido Lenz[1,2*], Giovana R. Onzi[3], Luana S. Lenz[1,2],
Julieti H. Buss[1,2], Jephesson A. dos Santos[1,2] and Karine R. Begnini[1,2]

Abstract

Heterogeneity is a pervasive feature of cancer, and understanding the sources and regulatory mechanisms underlying heterogeneity could provide key insights to help improve the diagnosis and treatment of cancer. In this review, we discuss the origin of heterogeneity in the phenotype of individual cancer cells. Genotype-phenotype (G-P) maps are widely used in evolutionary biology to represent the complex interactions of genes and the environment that lead to phenotypes that impact fitness. Here, we present the rationale of an extended G-P (eG-P) map with a cone structure in cancer. The eG-P cone is formed by cells that are similar at the genome layer but gradually increase variability in the epigenome, transcriptome, proteome, metabolome and signalome layers to produce large variability at the phenome layer. Experimental evidence from single-cell -omics analyses supporting the cancer eG-P cone concept is presented, and the impact of epimutations and the interaction of cancer and tumor microenvironmental eG-P cones are integrated with the current understanding of cancer biology. The eG-P cone concept

Background: Recent efforts of genome-wide gene expression profiling analyses have improved our understanding of the biological complexity and diversity of triple-negative breast cancers (TNBCs) reporting, at least six different molecular subtypes of TNBC namely Basal-like 1 (BL1), basal-like 2 (BL2), immunomodulatory (IM), mesenchymal (M), mesenchymal stem-like (MSL) and luminal androgen receptor (LAR). However, little is known regarding the potential driving molecular events within each subtype

Annals of Oncology

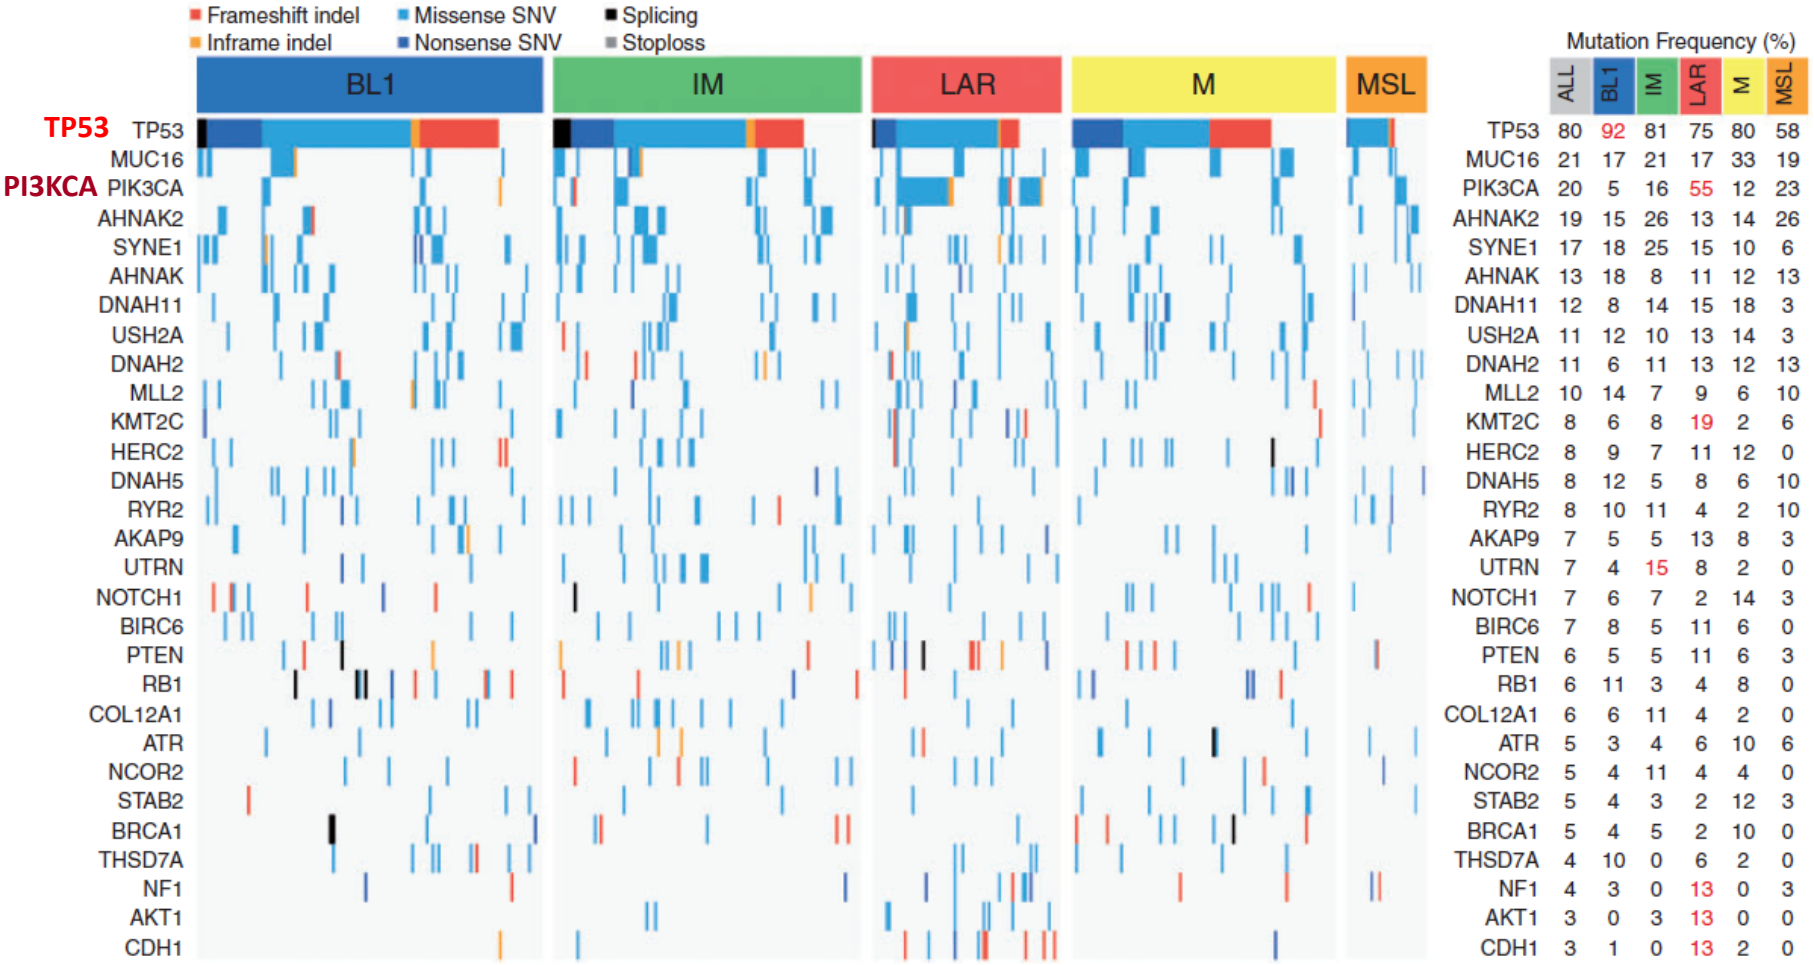

Figure 1. Mutational landscape of TNBC molecular subtypes. Frequencies of mutations across each TNBC molecular subtype according to the different types of mutations. Only genes mutated at a frequency >10% in at least one subtype are displayed. Significant differences (FDR < 0.05) are shown in red (right panel).

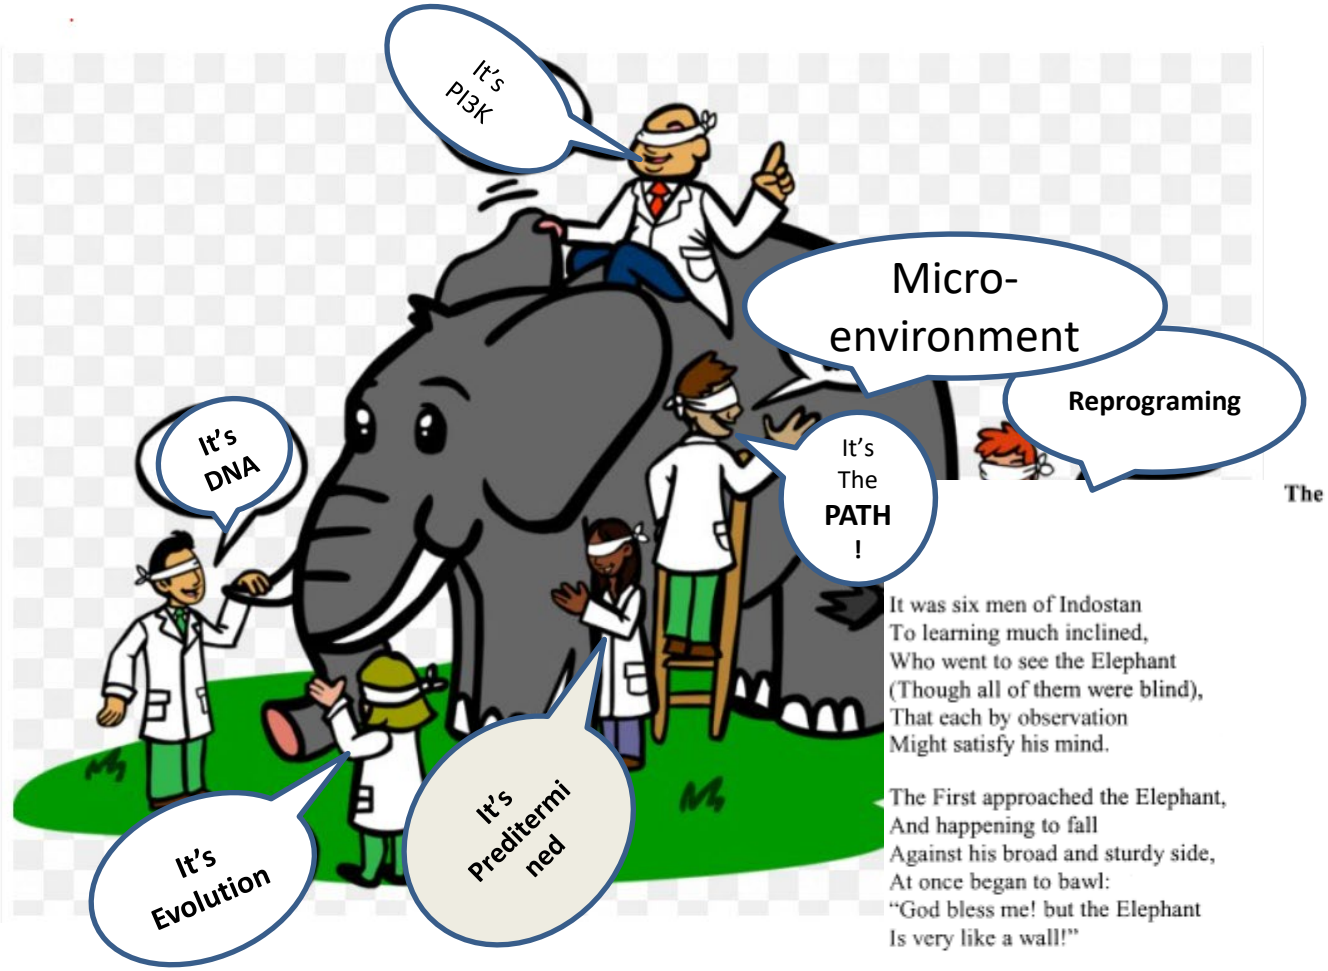
- **Evolutionary Adaptation (Predeterminism)**



The Blind Men and the Elephant
John Godfrey Saxe
(1816-1887)

It was six men of Indostan
To learning much inclined,
Who went to see the Elephant
(Though all of them were blind),
That each by observation
Might satisfy his mind.

The First approached the Elephant,
And happening to fall
Against his broad and sturdy side,
At once began to bawl:
"God bless me! but the Elephant
Is very like a wall!"

The Second, feeling of the tusk,
Cried, "Ho! what have we here
So very round and smooth and sharp?
To me 'tis mighty clear
This wonder of an Elephant
Is very like a spear!"

The Third approached the animal,
And happening to take
The squirming trunk within his hands,
Thus boldly up and spake:
"I see," quoth he, "the Elephant
Is very like a snake!"

The Fourth reached out an eager hand,
And felt about the knee.
"What most this wondrous beast is like
Is mighty plain," quoth he;
"'Tis clear enough the Elephant
Is very like a tree!"

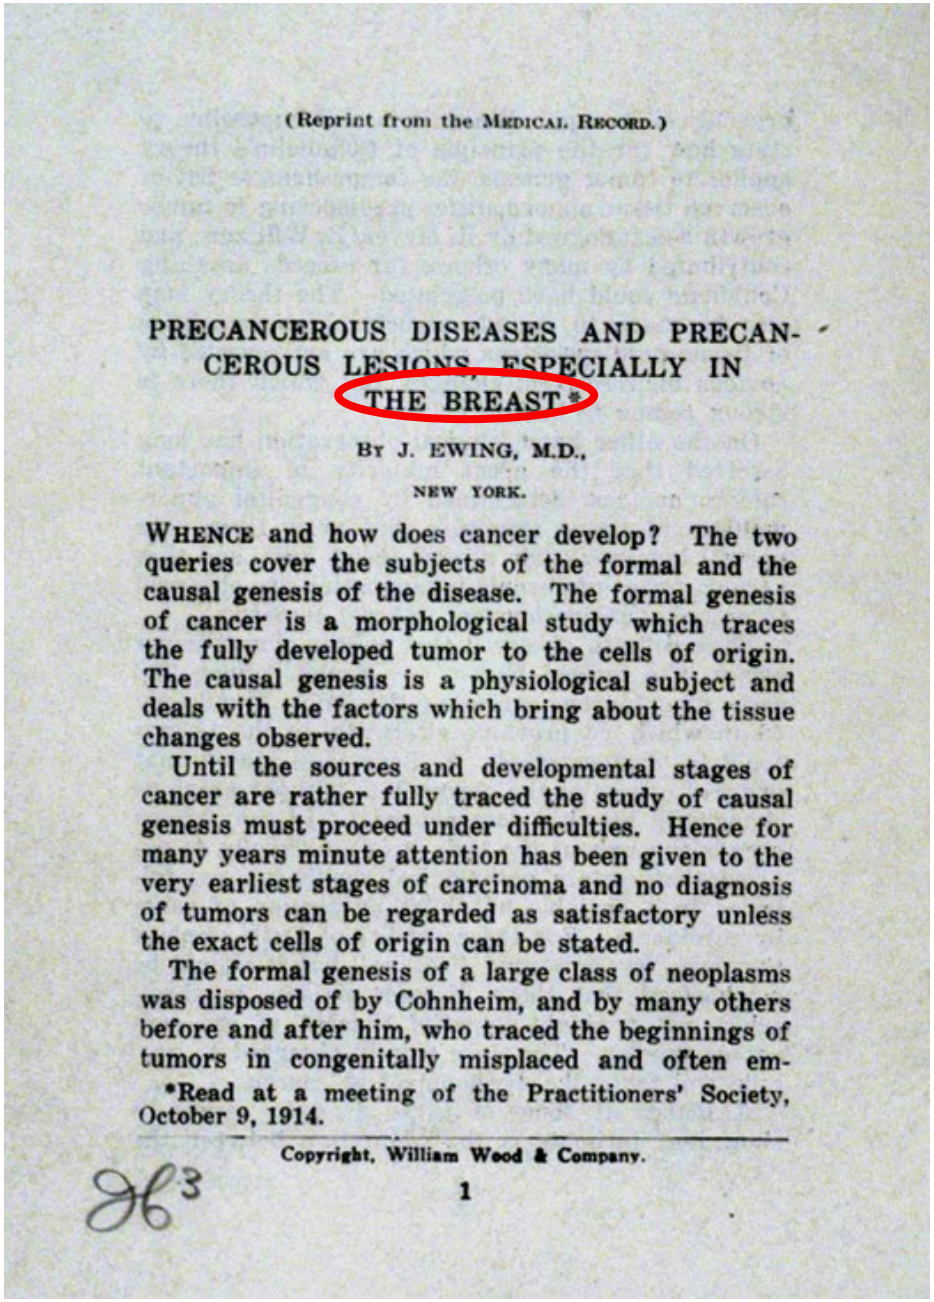
The Fifth, who chanced to touch the ear,
Said: "E'en the blindest man
Can tell what this resembles most;
Deny the fact who can
This marvel of an Elephant
Is very like a fan!"

The Sixth no sooner had begun
About the beast to grope,
Than, seizing on the swinging tail
That fell within his scope,
"I see," quoth he, "the Elephant
Is very like a rope!"

And so these men of Indostan
Disputed loud and long,
Each in his own opinion
Exceeding stiff and strong,
Though each was partly in the right,
And all were in the wrong!

Our Clinical History:
The limits of inferential Logic

WORD "PRECANCER": FIRST USED AND DESCRIBED IN 1913



(Reprint from the MEDICAL RECORD.)

PRECANCEROUS DISEASES AND PRECANCEROUS LESIONS, ESPECIALLY IN THE BREAST*

BY J. EWING, M.D.,

NEW YORK.

WHENCE and how does cancer develop? The two queries cover the subjects of the formal and the causal genesis of the disease. The formal genesis of cancer is a morphological study which traces the fully developed tumor to the cells of origin. The causal genesis is a physiological subject and deals with the factors which bring about the tissue changes observed.

Until the sources and developmental stages of cancer are rather fully traced the study of causal genesis must proceed under difficulties. Hence for many years minute attention has been given to the very earliest stages of carcinoma and no diagnosis of tumors can be regarded as satisfactory unless the exact cells of origin can be stated.

The formal genesis of a large class of neoplasms was disposed of by Cohnheim, and by many others before and after him, who traced the beginnings of tumors in congenitally misplaced and often em-

American Cancer Society Guidelines for the Early Detection of Cancer

Screening tests are used to find cancer *before* a person has any symptoms. Here are the American Cancer Society's recommendations to help guide you when you talk to your doctor about screening for certain cancers.

Health care facilities are providing cancer screening during the COVID-19 pandemic with many safety precautions in place. The American Cancer Society Get Screened campaign encourages people to start or restart their recommended cancer screenings. Regular screenings can help find and treat pre-cancers and cancers early, before they have a chance to spread. Visit Get Screened to learn about screening tests and what you can do

THE THEORY OF BIOLOGIC PREDETERMINISM: ITS QUESTIONABLE USEFULNESS AND VALIDITY AS A MEDICAL TOOL

LOUIS J. NOTKIN, M.D., C.M., F.A.C.G.,
Montreal

THE PHRASE "biologic predeterminism" has been recurring in the medical literature and at medical meetings with increasing frequency. Ian MacDonald first employed the phrase some years ago as "a synoptic expression for a biologic balance between host and neoplasm", established before the neoplastic process becomes clinically detectable.[1-3] Evidence provided in this publication "supported an obvious corollary: the outcome of

The term "biologic predeterminism" would appear to be an unfortunate one because its influence is not susceptible to measurement; it connotes an almost fatalistic approach and does not appear to have any value in furthering the interests of the patient with carcinoma of the stomach. It does convey a sense of frustration, hopelessness and mysticism, and unless clarified to the point of lucidity and usefulness should be dropped.

The concept that a longer history means a more favourable prognosis in a specific cancerous lesion appears to be a very confusing, though partially true, statement of fact. It is not at all illogical to believe that patients in whom carcinoma of the stomach is diagnosed, and who have a long history, may survive longer. What appears to be illogical is the implied assumption that it is therefore not harmful, and even beneficial, to delay operation. Such an assumption can be tragically harmful if, for instance, it should be finally demonstrated that the Alice-in-Wonderland concept of *The Later The Earlier* may have a very simple explanation,

belief that, should this concept become widely known and accepted, the already deeply rooted pessimism prevalent among general practitioners regarding the value of the surgical approach in cancer of the stomach will be reinforced. This is hardly desirable.

VIEWPOINT

Overdiagnosis and Overtreatment in Cancer
An Opportunity for Improvement

Laura J. Esserman, MD, MBA
University of California, San Francisco.

Ian M. Thompson Jr, MD
University of Texas Health Science Center at San Antonio.

Brian Reid, MD, PhD
Fred Hutchinson Cancer Research Center, Seattle, Washington.

Over the past 30 years, awareness and screening have led to an emphasis on early diagnosis of cancer. Although the goals of these efforts were to reduce the rate of late-stage disease and decrease cancer mortality, secular trends and clinical trials suggest that these goals have not been met; national data demonstrate significant increases in early-stage disease, without a proportional decline in later-stage disease. What has emerged has been an appreciation of the complexity of the pathologic condition called cancer. The word "cancer" often invokes the specter of an inexorably lethal process; however, cancers are heterogeneous and can follow multiple paths, not all of which progress to metastases and death, and include indolent disease that causes no harm during the patient's lifetime. Better biology alone can explain better outcomes. Although this complexity complicates the goal of early diagnosis, its recognition provides an opportunity to adapt cancer screening with a focus on identifying and treating those conditions most likely associated with morbidity and mortality.

Changes in cancer incidence and mortality[1] reveal 3 patterns that emerged after inception of screening (**Table**). Screening for breast cancer and prostate cancer appears to detect more cancers that are potentially clinically insignificant.[4] Lung cancer may follow this pattern if high-risk screening is adopted.[5] Barrett esophagus and ductal carcinoma of the breast are examples for which the detection and removal of lesions considered precancerous have not led to lower incidence of invasive cancer. In contrast, colon and cervical cancer are generally leads to overtreatment. This Viewpoint summarizes the recommendations from a working group formed to develop a strategy to improve the current approach to cancer screening and prevention.

Periodic screening programs have the potential to identify a reservoir of indolent tumors.[4] However, cancer is still perceived as a diagnosis with lethal consequences if left untreated.

An ideal screening intervention focuses on detection of disease that will ultimately cause harm, that is more likely to be cured if detected early, and for which curative treatments are more effective in early-stage disease. Going forward, the ability to design better screening programs will depend on the ability to better characterize the biology of the disease detected and to use disease dynamics (behavior over time) and molecular diagnostics that determine whether cancer will be aggressive or indolent to avoid overtreatment. Understanding the biology of individual cancers is necessary to optimize early detection programs and tailor treatments accordingly. The following recommendations were made to the National Cancer Institute for consideration and dissemination.

Physicians, patients, and the general public must recognize that overdiagnosis is common and occurs more frequently with cancer screening. Overdiagnosis, or identification of indolent cancer, is common in breast, lung, prostate, and thyroid cancer. Whenever screening is used, the fraction of tumors in this category increases. By acknowledging this consequence of screening, ap-

OVERDIAGNOSIS

DEFINITION: A SETTING IN WHICH DIAGNOSES INCREASE (OFTEN MARKEDLY) IN A POPULATION THAT HAS A STABLE OR DECLINING RATE OF DEATH FROM THAT DISEASE.

Connecting Cancer to Its Causes Requires Incorporation of Effects on Tissue Microenvironments

James DeGregori[1]

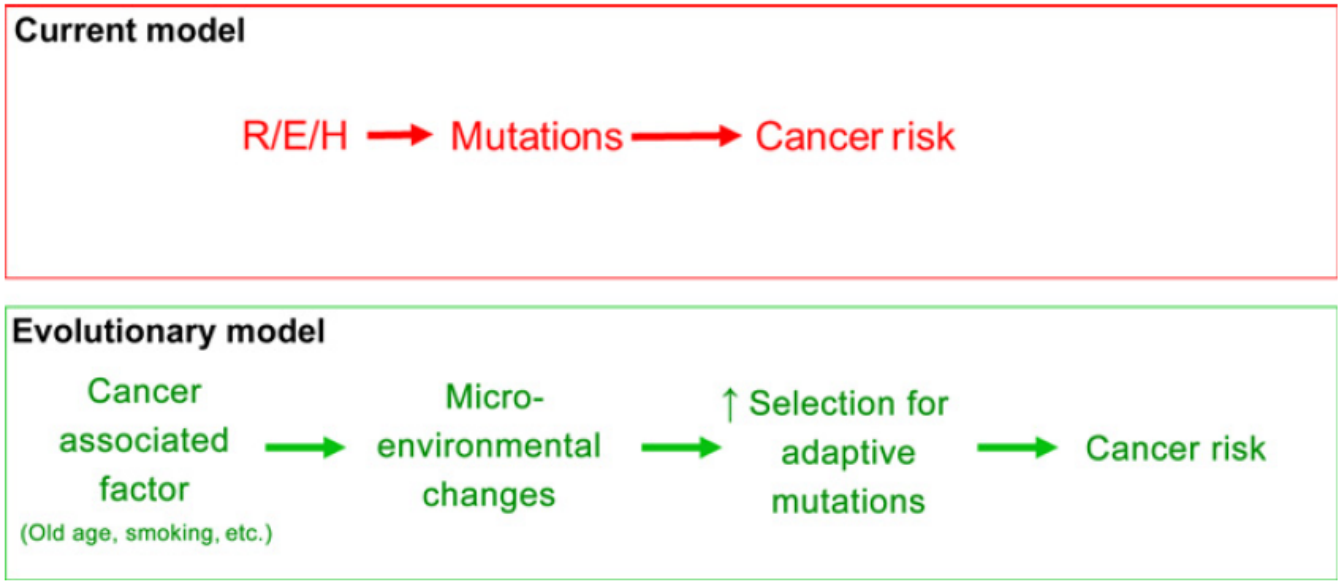

Figure 1.

Models connecting cancer to its causative contexts. Top, according to the current paradigm that forms the foundation for the Tomasetti and colleagues model, the primary role of R, E, and H in determining cancer risk is through increasing mutational burden in tissue stem cells. Bottom, an alternative model posits that the major impact for contexts like old age and environmental exposures on cancer risk is through alterations in tissue microenvironments that promote selection for adaptive mutations that contribute to cancer development. Adaptive mutations could emanate from R, E, and/or H, and increases in mutational burden from R, E, and/or H should increase cancer risk. However, the impact of cancer-associated factors on selection will have a much greater deterministic role.
